What is the complex modulus obtained from a dynamic mechanical test?

Equation (7) shows that the complex modulus obtained from a dynamic mechanical test consists of "real" and "imaginary" parts. The real (storage) part describes the ability of the material to store potential energy and release it upon deformation.

What is the difference between storage modulus and dynamic loss modulus?

The storage modulus is often times associated with "stiffness" of a material and is related to the Young's modulus, E . The dynamic loss modulus is often associated with "internal friction" and is sensitive to different kinds of molecular motions, relaxation processes, transitions, morphology and other structural heterogeneities.

What are the characteristics of a material in the DMA?

Often seen in the DMA as step changes in E' at low temperature. Toughness The ability of a material to absorb mechanical energy without fracturing or deforming. Ultimate strength The greatest stress a material can withstand without failing, breaking apart.

What is a DMA test?

In DMA measurements, the viscoelastic material behavior of solid-like samples is analyzed. To determine the time- and temperature-dependent deformation or flow characteristics, the specimen is set under a certain sinusoidal stress (or strain) and the material's response is measured.

How does a DMA instrument measure viscoelastic properties?

To do so, DMA instrument applies an oscillating force to a material and measures its response; from such experiments, the viscosity (the tendency to flow) and stiffness of the sample can be calculated. These viscoelastic properties can be related to temperature, time, or frequency.

How can DMA detect a viscoelastic variable?

DMA can detect and analyze viscoelastic variables like storage modulus, loss modulus, and loss tangent, as well as their dependence on temperature and frequency. The T_g and the temperature dependency of the modulus can both be studied via temperature dispersion measurements.

The onset point of storage modulus and the peak of loss modulus were identified at a lower temperature in NET measurements, indicating that the glass transition happened first in this DMA machine. While this event was identified at around 51.6 °C in NET, it was noted at 58.6 °C in PE Set 1, at 56.9 °C in PE Set 2 and at 57 °C in TA.

Dynamic Mechanical Analysis (DMA) is a characterization method that can be used to study the behavior of materials under various conditions, such as temperature, frequency, time, etc. The test methodology of DMA, which aims mainly at the examination of solids, has its roots in rheology (see also "Basics of rheology"), a scientific discipline that studies the viscoelastic properties of ...

Dynamic mechanical analysis is carried out by applying a sinusoidally varying force to a test specimen and measuring the resulting strain response. By analyzing the material response over one cycle, its elastic-spring-like storage modulus and its viscous or flow-like loss (imaginary) modulus can be determined.

If storage modulus is greater than the loss modulus, then the material can be regarded as mainly elastic. Conversely, if loss modulus is greater than storage modulus, then the material is predominantly viscous (it will dissipate more energy than it can store, like a flowing liquid).
