How does a storage water heater work?

A single-family storage water heater offers a ready reservoir -- from 20 to 80 gallons -- of hot water. It operates by releasing hot water from the top of the tank when you turn on the hot water tap. To replace that hot water, cold water enters the bottom of the tank through the dip tube where it is heated, ensuring that the tank is always full.

The majority of water heaters use much less energy when exclusively heating water. This is designed to heat water to a given temperature and keep it at a constant level, ready for immediate use. However, the boiler is designed to supply hot water for heating systems and household use, which could appear inefficient.

As a result, tankless water heaters deliver a constant supply of hot water. You don't need to wait for a storage tank to fill up with enough hot water. However, a tankless water heater's output limits the flow rate. Typically, tankless water heaters provide hot water at a rate of 2-5 gallons (7.6-15.2 liters) per minute.
