

Moon size

The Moon is an astronomical body orbiting Earth as its only natural satellite. It is the fifth-largest satellite in the Solar System, and by far the largest among planetary satellites relative to the size of the planet that it orbits (its primary).

How Big is the Moon Compared to Earth? Quick Answer: The Moon has a surface area of 14.6 million square miles (38 million square km), which is 27% that of Earth's. The Moon is also 81 times less massive than the Earth. While it might not sound like very much, the Moon's surface area of 14.6 million square miles (38 million square km) is greater than the total of these five ...

Our Universe is really vast and empty, though a few grains of matter dotting the cosmic void, from small dust grains to the biggest stars. Between small planets in the solar system and the biggest stars, the size difference is enormous, for example, the diameter of the star Betelgeuse is 141,863 times larger than the diameter of the Earth.

The Moon shining brightly in the night sky looks really big as compared to all the other stars twinkling beyond. Is this an illusion or is the Moon really big? Perceiving the Moon to be big by looking at it is not a real measure of the Moon's actual size. What we see is actually a [...]

Below is a list of moons in the solar system, based on size. This list features natural satellites from each planet. Non-direct measurements of moons, especially small and far away moons can give inaccurate measurements, making this list potentially unreliable. Take some of ...

Curiosity's view of the Martian moons: Phobos passing in front of Deimos - in real-time (video-gif, 1 August 2013). Speculation about the existence of the moons of Mars had begun when the moons of Jupiter were discovered. When Galileo Galilei (1564-1642), as a hidden report about his having observed two bumps on the sides of Saturn (later discovered to be its rings), used the ...

Overview. The Moon makes Earth more livable by moderating our home planet's wobble on its axis, leading to a relatively stable climate. It also causes tides, creating a rhythm that has guided humans for thousands of years. The Moon ...

How Big Is The Moon? The moon has a radius of 1,080-miles (1,737-kilometers). This means that the moon's diameter is 2,159-miles (3,475-kilometers) across. For comparison, the diameter of Earth is 7,918-miles (12,742-kilometers). This shows that the moon is approximately a quarter the width of Earth.

Deimos has a diameter of 7.5 miles (12 kilometers) and was 12,800 miles (20,500 kilometers) from the rover at the time of the image. Phobos has a diameter 14 miles (22 kilometers) and was 3,900 miles (6,240

Moon size

kilometers) from the rover at the time of the image.

Europa is the puniest of the Galilean moons. It is covered with ice. There are mysterious streaks that cover the moon's surface. Scientists think a water ocean might exist beneath the layer of ice, possibly even holding life.

Our Moon has a mean radius of 1,737 kilometers / 1,079 miles, while its polar radius is 1,736 km / 1,078 mi, and its equatorial radius is 1,738 km / 1,079 mi. The Moon's ...

Biggest To Smallest. Here you can learn about the 30 largest moons (by diameter) in the solar system! There are over 180 moons that orbit the planets and dwarf planets. The largest 19 moons in the list below are large enough to have been rounded by their own gravity (this is called being in hydrostatic equilibrium). If these moons were directly orbiting the Sun, that'd be referred to as ...

Size and Distance. With a radius of about 1,080 miles (1,740 kilometers), the Moon is less than a third of the width of Earth. If Earth were the size of a nickel, the Moon would be about as big as a coffee bean. The Moon is an average of ...

The moon likely has a very small solid iron core. (Image credit: Karl Tate, SPACE) The moon's rocky mantle is about 825 miles (1,330 km) thick and made up of dense rocks rich in iron and ...
