It has a much higher energy density than you normally get with super-capacitors." To illustrate the difference

between a battery and a capacitor, Voller explained that if you put a standard capacitor into a mobile phone, it would reach full charge in about a minute, but in use it would be completely exhausted after three minutes.

The main problem in such systems is building an energy storage device capable of rapidly storing large amounts of energy. One approach is to use an electrical generator which will convert kinetic energy to electrical energy and store it in a supercapacitor. This energy can later be reused to provide power for acceleration.

The two primary attributes of a capacitor are its energy density and power density. For either measure, the density can be calculated as a quantity per unit mass or per unit volume. The energy E stored in a capacitor is directly proportional to its capacitance: $E= 1 \ 2 \ CV$. 2. (3) In general, the power P is the energy expended per unit time.
