However, their working principles are different. A turbo runs when the exhaust gasses wind the turbine but a supercharger generates power from the rotating crankshaft. This working principle is actually less efficient because it uses energy from the car's engine while a turbo makes use of the wasted energy. A car with a supercharger engine.

A turbine (that's the "turbo" part of the name) is powered by the engine's exhaust, cooling and slowing it down in the process, and through a shaft it connects to a compressor (or "supercharger," which donates its back half to the name) which forces air into the cylinders at higher-than-atmospheric pressure.

CAES systems are categorised into large-scale compressed air energy storage systems and small-scale CAES. The large-scale is capable of producing more than 100MW, while the small-scale only produce less than 10 kW [60].The small-scale produces energy between 10 kW - 100MW [61].Large-scale CAES systems are designed for grid applications during load shifting ...

I just ordered a Turbo Twist, upgraded knob and the energy storage cylinder (just to have the option of a longer spin). Since my control panel isn't huge, I like the small bottom profile.
