Why does a capacitor need a large capacitance value?

Fig. 1), energy is stored in capacitors on the power bus. This requires a large capacitance value because the allowed voltage of high-voltage-energy storage (HVES) stores the energy on a capacitor at a higher voltage and then transfers that energy to the power bus during the dropout (see Fig. 3). This allows a smaller capacitor to be used because a

What is high voltage energy storage (HVES)?

high-voltage-energy storage (HVES) stores the energy on a capacitor at a higher voltage and then transfers that energy to the power bus during the dropout (see Fig. 3). This allows a smaller capacitor to be used because a large percentage of the energy stored in the capacitor is released during the dropout. Fig. 4. PCB energy density with V₂

When connecting a capacitor across L1 and L2, you must use a voltage-rated capacitor of at least 125% of the peak line voltage, which is 1.414 times RMS (root mean square) voltage. In other words, if you have a 120 VAC supply, you need at least a 150 VAC rated capacitor ($1.25 \times 120 \text{ V} = 150 \text{ V}$).

A capacitor is an electrical component that stores energy in an electric field. It is a passive device that consists of two conductors separated by an insulating material known as a dielectric. When a voltage is applied across the conductors, an electric field develops across the dielectric, causing positive and negative charges to accumulate on the conductors.

This makes supercaps better than batteries for short-term energy storage in relatively low energy backup power systems, short duration charging, buffer peak load currents, and energy recovery systems (see Table 1).
